Nostrian Conquest

Player Manual

A Rust recreation inspired by the classic 1990s BBS door game Esterian Conquest.

Built for localhost and BBS play. A Nostr GameServer path is planned.

All code, UI, and assets in this edition are original. Not affiliated with any original release.

Revision date: October 11, 2026

1. Introduction

Beyond the mapped frontiers of the old Nostrian dominion lies a small galaxy of contested solar systems. The old masters are gone. Their stations are silent, their patrols vanished, and their subjects left with fleets, industry, and enough knowledge to build empires.

You rise as one of the new Star Masters. From a single world and a few small fleets, you must tax, build, scout, bargain, threaten, and strike before rival powers can do the same. Some systems will join your banner willingly. Others will require persuasion from orbit.

Each maintenance marks the passage of a year. In that span, fleets cross the dark between stars, colonies grow or starve, alliances turn cold, and wars are decided by distance, industry, mathematics, and will.

Nostrian Conquest is a Rust recreation inspired by the classic 1990s BBS door game Esterian Conquest. All code, UI, and assets in this edition are original. It is not affiliated with any original release.

In homage to the 1990s door-game pioneers and to the ancient dreamers, strategists, and storytellers whose visions of galactic dominion still light the way among these stars.

2. Connecting to a Game

2.1. Three Ways to Play

Nostrian Conquest has three practical ways to play.

The direct path is **Localhost**. In that mode you or your sysop runs `nc-game` directly on the same machine. Use this for solo play, hotseat testing, and trusted same-machine sessions. If you are setting that up yourself, see the **Sysop Manual** section **Localhost Session Setup**.

The classic path is **BBS**. In that mode you log into a bulletin board with a terminal client and launch the game from the doors menu. The sysop stages `nc-door` behind the BBS. If you are the sysop, see the **Sysop Manual** section **BBS Door Setup**.

The planned network path is **Nostr GameServer**. That path is still under development. For now, treat localhost and BBS as the normal ways to play.

2.2. Finding New Games

If you are joining a private localhost campaign, your sysop tells you which machine and player slot to use.

If you are joining a BBS campaign, connect to the bulletin board normally and launch the game from the doors menu. Your sysop may reserve a seat for your BBS alias, or may leave open seats available from the first-time join menu.

If you are waiting for the Nostr GameServer path, watch the main project docs. It is planned, but it is not the normal join path yet.

2.3. Joining a Game

For localhost play, the normal direct launch is:

```
nc-game --dir /path/to/mygame --player 1
```

Your sysop may give you a different player number or run the command for you on the local machine.

For BBS play, the sysop launches `nc-door` from the board software and the caller enters through the normal first-time or returning-player flow inside the game. If your BBS alias is reserved for a seat, the door routes you there automatically.

3. Quick Start: Gameplay Basics

3.1. Your Objective

Your objective is simple: become Emperor by dominating rivals or eliminating every serious threat.

You begin with one planet at 100 production and four fleets — two carrying an ETAC and cruiser for colonization, and two lone destroyers for screening and early contact. Set a tax rate around 50–65% on your homeworld, and use the revenue to build ships, armies, batteries, and starbases. Keep taxes low on new colonies so they develop quickly.

Each round represents one year. You submit orders during the year, and maintenance resolves all empires simultaneously on an internal 52-week timeline. Reports are dated as `Stardate WK/YYYY` (week/year).

3.2. Turn Progression

There is no "End Turn" button. You set your economy, assign your missions, and log off. The sysop or schedule decides when maintenance runs. When it does, the game resolves every empire at once, advances the year, and writes your next set of reports.

If maintenance runs while you are logged in, the game cannot save your next change. It says so on the menu notice line: "Maintenance has run; your last change was not saved. Log in again." Log in again to carry on. In a BBS door the session ends and returns you to the BBS.

3.3. Assets You Can Build

The table below lists everything your planets can produce. **AS** is Attack Strength (firepower) and **DS** is Defense Strength (hull/shields).

Item	Cost	Size	Speed	AS	DS	Purpose
Destroyer	05	S	6	10	08	Fast combat, screening, defense
Cruiser	15	M	5	30	30	Balanced combat
Battleship	45	L	4	90	100	Heavy combat
Scout	15	S	6	00	10	Reconnaissance
Troop Transport	05	M	5	00	10	Deliver armies
ETAC	20	L	3	00	20	Colonize raw planets (reusable)
Ground Battery	20	L	–	90	20	Planetary defense
Army	02	S	–	10	10	Surface defense and capture
Starbase	50	L	1	100	120	Defense, production boost

3.4. Fleet Missions (Summary)

Fleet missions fall into three classes. *One-shot* missions travel, act, and then fall back to Hold Position. *Persistent* missions stay in force until you replace them or game rules cancel them. *Hostile* missions attack the year they reach orbit around the target world. Bombard keeps

bombarding each year; Invade and Blitz fall back to Hold Position in orbit after the assault, win or lose. Section 7.1 explains how long a trip takes.

No	Mission	Type	Requirements	On Arrival / Completion
00	Hold position	Persistent	Any ships	Idle at current position
01	Move to sector	One-shot	Any	Reverts to Hold on arrival
02	Seek Home	One-shot	Any	Reverts to Hold; retargets if destination captured
03	Patrol	Persistent	Any	Patrols sector continuously
04	Guard starbase	Persistent	Combat ships	Escorts starbase continuously
05	Guard/blockade world	Persistent	Combat ships	Blockades world continuously
06	Bombard world	Hostile	Combat ships	Bombards when in orbit at tick start
07	Invade world	Hostile	Combat + loaded transports	Invades when in orbit at tick start
08	Blitz world	Hostile	Loaded transports (combat recommended)	Blitzes when in orbit at tick start
09	View	One-shot	Any	Dives in, scans, climbs back out; reverts to Hold
10	Scout sector	Persistent	At least one scout	Reports each turn while on station
11	Scout system	Persistent	At least one scout	Reports each turn while on station
12	Colonize world	One-shot	At least one ETAC	Colonizes if unowned; ETAC survives for reuse
13	Join Fleet	Persistent	Any	Chases host until merge; abandons if host lost
14	Rendezvous	Persistent	Any	Waits at sector; lowest fleet ID becomes host
15	Salvage	One-shot	Any	Scraps ships for half their build cost

4. Forces at Your Command

You control five major force types: planets, ships, starbases, armies, and ground batteries.

4.1. Planets

Planets are the foundation of your empire. Each one has a **Potential Production** — the ceiling it can reach at full efficiency, ranging from 10 to 150 across the galaxy — and a **Production**, which is what the planet can actually deliver right now. Production grows toward Potential over time, and the speed of that growth depends heavily on your tax rate.

Taxes convert Production into spendable build points each year. See Section 5 for the full tax rate, growth, and starbase economics model.

4.2. Ships

Ships operate in fleets. A fleet always moves at the speed of its slowest member and can hold anywhere from one to **3,000 ships** of mixed types.

Ship Type	Cost	Speed	Size	AS	DS	Tactical Role
Destroyer	05	6	S	10	08	Fast raider and line support. Escapes heavy fleets. Good for fast response and interception.
Cruiser	15	5	M	30	30	Balanced fighter. About 3x the power of a destroyer.
Battleship	45	4	L	90	100	Heavy firepower anchor. About 3x the power of a cruiser. Slow but durable.
Scout	15	6	S	00	10	Stealthy spy. A lone scout is hardest to detect.
Transport	05	5	M	00	10	Unarmed. Carries one army. Essential for conquest.
ETAC	20	3	L	00	20	Colony ship. Reusable — survives colonization.

4.2.1. Reading Fleet Compositions

Wherever the game lists ships in one line, it uses one notation, and always the same order: scouts, battleships, cruisers, destroyers, loaded transports, empty transports, ETACs, starbases. A planet's stardock and build queue read the same way, with armies (`AR`) and ground batteries (`GB`) after the starbases. Each token is a ship code, the total number of ships of that kind, and, when some of them are crippled, a `!` and the number crippled. The total always includes the crippled ships. A single ship still shows its count, a kind the fleet lacks is left out, and `!0` is never written.

Token	Meaning
`SC1`	One scout.
`BB2!1`	Two battleships; one is crippled.
`CA12!3`	Twelve cruisers in all; three of them are crippled.
`DD8`	Eight destroyers, none crippled.
`TT*4!1`	Four loaded transports; one is crippled.
`TT5`	Five empty transports.
`ETAC2`	Two ETACs.
`SB1!1`	One starbase, crippled.

A fleet of `BB2!1 CA12!3 DD8 TT*4!1 TT5 ETAC2` therefore holds nine transports, five empty and four loaded: the star marks cargo, the bang marks damage, and the two never mix. The short legend, repeated in the in-game help, is: `!n = crippled ships included in total; TT* = loaded transports`.

A fleet counts its crippled transports once, whether they carry armies or not. The game lists them against the loaded transports first, the same order in which transports are lost in battle.

In the Fleet List the Ships cell is narrow. When it cannot hold a damaged fleet's whole composition, it ends in `+!`: the `+` says the line was cut short, and the `!` says the fleet has crippled ships. A lone `!` never means the whole fleet is crippled.

4.3. Starbases

Starbases are large space fortresses (Cost: 50, AS: 100, DS: 120). In orbit, they strengthen a world's defense and economy. They help weak colonies grow at sensible tax rates, and they let a planet spend up to **5x** its Production in one turn when enough points have been saved (see Section 5). They are not a license to tax a world to death. In deep space they serve as watch posts with slightly more firepower than a battleship, but they crawl at speed 1.

Unlike ships, starbases do not belong to fleets. You commission them one at a time from stardock and move them through the **Starbase Command** submenu. Older docs sometimes say a starbase is "hauled." In practice, that just means moving a very slow unit. You may order combat fleets to escort a starbase with Mission 4 (Guard Starbase), but the starbase remains its own unit.

A starbase moves one sector a year. A base resting in orbit first spends a year climbing out to deep space. It enters orbit at its destination only if you own the world there; anywhere else it stops in deep space. Its escort, the guard fleet at rest beside it, rides along. Other guard fleets head for the base's new position whenever it changes sector or climbs out of a system, and a guard that reaches the base joins the escort, unless the two together would pass 3000 ships.

A starbase in orbit needs a friendly world beneath it. If you lose that world, the base leaves the system for deep space in its own sector. A base bound for a world you no longer own stops where it is and awaits new orders. Moving a starbase out of orbit also cancels every

build order of the world beneath it when those builds rely on the base: when a queued unit, or the whole queue, costs more than the world's Production and no other starbase rests in orbit there.

> **NOTE:** Starbases must be commissioned from stardock before they can be moved or provide orbital benefits. An uncommissioned starbase sitting in stardock has no effect.

4.4. Ground Forces

Armies (Cost: 2, AS: 10, DS: 10) defend your planets from invasion and are the only way to capture enemy worlds. Each troop transport carries one army, and a successful invasion requires landing enough armies to overwhelm the defending garrison.

Ground Batteries (Cost: 20, AS: 90, DS: 20) are immobile land-based cannons that offer massive firepower per cost — roughly equal to a battleship at less than half the price. During an invasion, all batteries must be destroyed before transports can land. During a blitz, surviving batteries fire directly on descending transports, inflicting heavy losses. If a planet is captured via blitz, any surviving batteries transfer intact to the new owner.

5. Economy and Taxes

Your empire runs on production. Every owned planet generates tax revenue each maintenance cycle, and that revenue pays for ships, defenses, and expansion. Managing the tension between short-term revenue and long-term growth is one of the deepest strategic challenges in the game.

5.1. Key Terms

Every planet has a **Potential Production** — the maximum productive capacity it can ever reach — and a **Production**, which is what it can deliver right now. Production grows toward Potential over time. A planet's **Revenue** is the tax it will add to its Treasury at the next maintenance, assuming your tax rate, the planet's owner, and its starbase stay as they are. Your empire's **Empire Revenue** is the sum of that revenue across all your planets. Any revenue a planet does not spend accumulates on it as its **Treasury** — the reserve of saved production points available to fund future builds. Each turn, how much of that treasury a planet can actually spend is limited by its **build capacity**; that per-turn spending limit is the planet's **Budget**.

5.2. Tax Revenue

The tax rate is empire-wide: you set one rate for all your planets. Revenue per planet per year is a fixed percentage of Production, and your empire's Empire Revenue is the sum of that revenue across all owned planets. The screens show next year's revenue, rounded to the nearest whole point, and setting the tax rate reports the new Empire Revenue. Production and the Treasury keep their fractions from year to year; only what you read and spend is a whole number. See Section 11 for the exact formula.

5.3. Growth Toward Potential

Each maintenance turn, every owned planet grows toward its Potential. Lower taxes grow faster. A planet at 30% tax develops far faster than one at 60%. Growth also slows as the planet nears its ceiling: each year a planet closes a share of its gap to Potential, so it comes close to Potential without reaching it on a fixed date. Every point of tax costs growth, and there is no free yearly minimum.

Growth is based on the gap to Potential and the remaining tax headroom. See Section 11 for the exact formula.

5.4. The 65% Tax Threshold

> **WARNING:** Setting taxes above **65%** can directly *reduce* Production on your planets, not just slow growth.

Below 65%, growth is always positive — lower is faster. Above 65%, a penalty kicks in that actively damages Production, and a mature planet settles below its Potential: a Potential-100 world taxed at 70% settles at Production 88 and earns 62 a year, and at 71% it settles at 86 and earns 61. A commissioned starbase does **not** remove this danger. Its value is that it

helps young colonies grow faster before you reach punitive tax rates, and it still preserves the powerful build-capacity bonus described below.

The recommended early-game rate is around 50–65%. Drop taxes on new colonies to accelerate their development. See Section 11 for the exact penalty and yearly update formulas.

5.5. Starbase Economic Effects

A commissioned starbase in orbit provides two major benefits. First, the planet's yearly production growth gets a strong boost when taxes are modest — half again as fast at **50% tax or lower**, fading steadily to nothing as taxes climb toward **65%**. This means underdeveloped planets with starbases catch up significantly faster when you are managing them sensibly, but the bonus is not meant to offset punitive taxes. A planet already at its Potential gains nothing from it. Second, the planet gains a **build capacity multiplier** — it can spend up to **5x** its Production on builds in a single turn, drawing from its treasury. Without a starbase, a planet can only spend up to 1x its Production per turn. See Section 11 for the exact bonus fade and build-capacity formulas.

More starbases at one world add defense, not growth or capacity. A starbase that is crippled in battle but survives keeps both bonuses.

> **NOTE:** These bonuses require an active, commissioned starbase in orbit — not an uncommissioned starbase sitting in stardock. The growth bonus needs a starbase of yours at rest in orbit of your world. The build-capacity bonus counts a starbase of yours in orbit, or on its way down to the planet's orbit, so a starbase arriving at a world can raise its budget a year before it raises its growth. A starbase of another empire counts for neither.

5.6. Treasury

Tax revenue that a planet does not spend accumulates in its **Treasury** — the planet's savings reserve. The treasury is what allows starbase worlds to execute large builds: up to 5x Production in a single turn. Each turn, a planet's **Budget** is the lesser of its treasury and its build capacity. That is what the build screen shows as **BUDGET** — how many production points remain uncommitted this turn. When maintenance processes a build queue, only the points actually spent that year are deducted from the treasury; unfinished builds keep their remaining cost for later turns. You spend whole points. The treasury keeps any fraction, and it can carry a debt: a negative treasury stays negative, buys nothing, and later revenue pays it down.

5.7. Newly Colonized Planets

A freshly colonized planet starts at Production 3 (or at its Potential, if that is lower) and with no treasury. It does not collect revenue or growth on the same maintenance turn that establishes the colony. Growth begins on the next maintenance turn. Each year growth is applied first and tax revenue is then credited on the grown Production, so at moderate tax rates most colonies have a small budget after their first full turn. Very small worlds, or colonies under low taxes, can still sit at zero budget for a turn or more, because the treasury only counts

whole points. The head start comes only with founding, never with capture, recapture, or recovery, and does not depend on the tax rate. Low taxes still develop new colonies fastest; they just fill the treasury more slowly at first.

5.8. Conquered Planets

When you capture an enemy planet by invasion or blitz, the planet's industry needs **two quiet years** before it is converted. It pays no revenue and does not grow in the next two maintenance turns, and it pays full revenue from the third. Its Revenue reads 0 until then. Plan your logistics around this delay.

5.9. Scorch Earth

Scorch Earth denies a world to an invader. The **Scorch** command sets the order, and the same command rescinds it. Setting it asks three confirmations; rescinding it asks one. The order changes nothing at once. It stays in force until you rescind it or the world is captured, and it first takes effect at the next maintenance, before the year's fighting, so it is already in force when an assault strikes that year.

Each year the order is in force, the planet's Production falls to between 30% and 49% of itself, never below 1, and its stored points fall to a tenth, or to their square root if that is smaller. The planet neither grows nor pays revenue, and its Revenue reads 0. Debt is left as it is. Potential Production is not touched, so a world that is not captured recovers by the normal growth rules once you rescind the order. Your maintenance report tells you each year what the order cost the planet.

6. Combat Mechanics

Battle reports are short, but the fighting is not random brawling. Combat is simultaneous and rule-driven. Both sides fire in the same round. Losses are then applied. This keeps battle outcomes clear, severe, and consistent.

6.1. The Rules of Battle

Each round, both sides fire at the same instant, and nobody fires first. Each side rolls one ten-sided die, and the roll decides how much of its total **Attack Strength (AS)** lands on the enemy: a quarter on 0–2, half on 3–5, and all of it on 6–9. A bigger fleet wins by bringing more AS, not by rolling on a better table. Rounds repeat until one side is destroyed or breaks off.

Damage reduces ships from "Nominal" to "Crippled" status before destroying them. All nominal ships must be crippled before any crippled ship is destroyed. A crippled ship fights at half strength in every later battle until it recovers on its own: a ship crippled this year fights crippled next year and the year after, and is whole from then on, with no order, payment, or shipyard. A fleet that rests in orbit of your world beside your starbase for a whole year gets its older cripples back a year sooner. The fleet screens show how many ships of each kind are crippled (see Section 4.2.1). Hits always target the combat line first — destroyers, cruisers, battleships, and starbases. Scouts, transports, and ETACs are protected as long as any combat-line ships remain, which means your non-combat vessels survive as long as your warships hold the line.

Each damage step costs the target's full **Defense Strength (DS)**: once to cripple a ship and again to finish it. Hits too few for the next step are not wasted. They carry over to the next round of the same battle, so even a small force wears down a big ship if it stays in the fight. Leftover hits last only as long as the battle. When it ends, whether by destruction, withdrawal, or the round limit, they are lost, and the next battle starts from zero, even against the same enemy fleet. A fleet that breaks off forfeits the hits it has built up against the enemy.

Three bonuses add to your die roll. A fleet that mixes at least two of destroyers, cruisers, and battleships gets a **combined arms bonus** of +1, so mix your composition when you can. A starbase fighting on your side adds another +1. An attack that catches the enemy unprepared adds a third +1 to the attacker's first round (see **Surprise** under Who Fights Whom). The bonuses never add more than +2, and a roll pushed past 9 counts as 9. An unmodified 9 is a critical hit that destroys one more enemy ship outright. In a draw, the defender wins. See Section 12 for the exact ROE thresholds, combat values, effectiveness table, and assault formulas.

6.2. Who Fights Whom

Fleets meet only when they share a sector **and** a depth. Each sector has two layers: deep space, and the solar system around its world (see Section 7.1). A fleet at least halfway down to a world is in its system. A fleet in orbit cannot see a fleet passing overhead in deep space, and neither can fight the other.

A year is 52 weeks. Each week, every fleet and starbase takes a turn, in an order drawn at random once a year. In its turn a fleet moves one week's distance, scans the alien fleets and

starbases sharing its sector and layer, and then carries out its order. Battles therefore happen in the middle of the year, wherever fleets happen to be that week, and the report carries that week's stardate.

Sighting. Each week a fleet has a chance of spotting each alien unit near it. Big fleets are easier to see than small ones: battleships and ETACs show most, then cruisers and transports, then destroyers; scouts add a little. A fleet in a solar system is five times easier to see than one in deep space, and a fast-moving fleet is easier to see than a slow one. A fleet at its target on a bombard, invade, or blitz mission is twenty times easier to see, and patrols, colonizers, and system scouts twice as easy. Starbases are fairly conspicuous.

How hard a fleet looks depends on its order. A patrol that has reached its sector looks ten times as hard as an ordinary fleet; a scout or a blockade on station, five times. Starbases look hardest of all. Spotting a unit once makes it easier to spot again. What one of your fleets or starbases learns about an alien unit, all of them know, until that unit moves to another sector or layer.

Identification. A fleet with ROE above 0 closes to identify what it spots, and so do patrols, scouts, and blockades on station. Any other fleet only reports a sensor contact. A fleet guarding a starbase stays with its base and does not close.

The decision. A fleet that identifies an alien fleet attacks it when:

- your empire has declared the fleet's owner an enemy (his declaration against you does not count);
- the alien fleet is in one of your solar systems, whatever its order, and even if its owner is neutral;
- your fleet is blockading a world and the alien fleet has come to bombard, invade, or blitz it, or to colonize it while it is unowned (this holds at any world, yours or not);
- both fleets are colonizing the same unowned world; or
- your fleet is on a bombard, invade, blitz, or colonize mission and the alien fleet guards the target world. If your ROE forbids that fight, your fleet aborts its mission and seeks home instead.

Any other alien fleet is ignored. A sector with no world is nobody's system.

Whether your fleet then attacks is decided by its ROE and the odds, the first time it identifies a target as on every later week (see Section 12). Identifying an enemy first commits nothing: a cautious fleet does not attack a stronger enemy just because it saw it first. For these odds each warship counts its attack strength — a destroyer 10, a cruiser 30, a battleship 90 — and a starbase 100, the same values the battle fires with. Scouts, transports, and ETACs count nothing, and a fleet without warships never attacks, whatever its ROE.

The odds are those of the sides as they would fight. Your fleets in the same sector and layer fight together, so each of them weighs all of them against all of the enemy's there: two fleets of five cruisers at ROE 6 would each refuse ten cruisers alone, and take them on together. Each of your fleets there volunteers under its own ROE: one that refuses the assembled odds stays out, and the others re-check without it. If the fleet that spotted the enemy is the one

that refuses, there is no attack that week; another willing fleet of yours attacks only when it spots and catches the enemy itself.

Intercept. A fleet with a higher maximum speed always catches its target. Otherwise the target may notice the attack and run. A stopped target cannot run; a moving one escapes more often the faster it moves and the slower its pursuer. A target that already knows the attacker rarely notices it coming, and then it stays to fight only if its own ROE accepts the odds.

Battle. Every battle is between two empires. Your side is your fleets in the sector and layer that volunteered; the enemy's side is all of his fleets there, whatever their ROE — a fleet that is attacked fights, ROE 0 included — with the starbase that was attacked or that a guard fleet among them guards. Nobody else joins: not a third empire, not allies, not fleets that arrive later in the week. The fleet that started the attack spends the week fighting instead of moving. A fight does not change the empires' diplomacy.

Surprise. Your empire remembers, in each sector and layer where it has a fleet or a starbase, which opposing empires it has spotted there. Whenever any of your fleets or starbases there spots an alien unit, its empire goes into that memory, and so does the empire of any fleet you fight there. All of your fleets and starbases in that sector and layer share it. The memory lasts, from week to week and year to year, for as long as you keep a fleet or a starbase in that sector and layer; when the last one leaves or is destroyed it is gone, and an opponent that leaves and comes back does not erase it. It is local readiness, not knowledge of the whole empire: what a scout learned in another sector does nothing here.

An attack is a **surprise** when the defending empire's memory there does not include the attacker's empire: none of its fleets or starbases there has spotted the attacker, and the two have not fought there. The attacking side then adds 1 to its die in the first round of the battle. The bonus counts within the +2 limit, an unmodified 9 is still the only critical hit, and a pursuit round never gets it. Only the attacker can surprise: a defender that was hidden earns nothing for it. Spotting is not the same as identifying, and a fleet that spots an enemy and declines to attack, because of its ROE or because the odds are against it, still remembers. The battle report says "We attacked by surprise." or "The enemy attacked by surprise." Staying unseen therefore keeps your chance of a surprise, and watching a system keeps your defenders ready.

Starbases scan, and what they identify every fleet of their empire knows, but they never start a fight and never join one to attack. A fleet attacks a starbase only if its empire has declared the base's owner an enemy, or if the base protects the world the fleet has come to bombard, invade, or blitz. Either way the fleet weighs the base, its guard, and the owner's other fleets there against its own side, and if the odds are against it, it avoids the base or aborts its mission.

Blockades. A blockade does not stop a neutral fleet leaving the world or arriving at it, unless the arrival comes to attack or colonize it. A blockade catches a departing fleet only if your empire has declared that fleet's owner an enemy, and only if it spots and intercepts the fleet in the few weeks the fleet takes to climb out of orbit.

6.3. Tactical Roles and Split Fire

Combat is more than just a numbers game. Different ship classes perform specific tactical roles based on how they deliver fire. Hits generated by a task force are split into two pools:

- **Suppression Fire (Cruisers and Battleships):** These heavy vessels provide volume and suppression. Their hits are dispersed across the enemy fleet, reducing nominal ships to a **crippled** state. This effectively knocks enemy guns offline and wins the immediate field, but it does not always result in permanent kills.
- **Execution Fire (Destroyers and Starbases):** These units use **focus fire** to eliminate specific targets. Their hits bypass the crippled state and allocate directly to the **destroyed** pool, paying the full 2x DS cost to blow ships up one by one.

This creates a deadly pair. Heavy ships soften the line. Destroyers and starbases finish it. Each pool carries its own leftover hits: suppression hits never pay for an execution kill, and execution hits never pay for a cripple.

> **NOTE:** All planetary return fire from ground batteries is treated as **Execution Fire**. Fortified worlds do not "soften" an attacker; they destroy him.

6.4. Fleet Limits

A fleet can contain as few as one ship and as many as **3,000 ships** of mixed types. A fleet always moves at the speed of its slowest member.

6.5. Rules of Engagement (ROE)

You assign an ROE level (0–10) to control when your fleet attacks. ROE 0 never attacks, but a fleet on ROE 0 that is attacked still fights the first exchange. Any higher ROE attacks a hostile fleet when the force ratio of the two sides, your fleets in the sector and layer against the enemy's, meets the ROE threshold (see Who Fights Whom); seeing the enemy first changes nothing. ROE also decides when your fleet breaks off a battle: after the compulsory first exchange it checks the same odds after every exchange and leaves as soon as they fail (see Withdrawal and Retreat).

The full ROE threshold table is collected in Section 12.

Non-combat fleets (scouts, transports, ETACs only) are treated as ROE 0 automatically. Giving such a fleet any order sets its ROE to 0, and so does a detach or transfer that leaves a fleet without a battleship, cruiser, or destroyer. A fleet that gains warships keeps its ROE, even ROE 0; set a new one with ROE (**C**). A fleet that Detach creates starts at ROE 6, or at 0 when it has no warships, whatever the donor's ROE is.

6.6. Withdrawal and Retreat

> **IMPORTANT:** Low ROE does not guarantee safety once combat begins.

Every battle opens with one compulsory exchange: both sides fire once, whatever their ROE. After it, and after every exchange that follows, each of your fleets in the battle checks its own

ROE against the odds as they now stand, your side's attack strength against the enemy's, and breaks off as soon as they fail. Every fleet whose ROE fails leaves at once, on both sides together, and the fleets that stay re-check the odds without them. A fleet that has left does not come back, even if the odds later turn in your favour. A fleet with no armed ship left, including one that has just lost its last warship, tries to escape at once, whatever its ROE. A starbase never breaks off; the fleets beside it, its guard included, leave under their own ROE like any other.

Losses are shared among your fleets in proportion to each fleet's eligible ships: of the ships the enemy's fire reaches, a fleet with eight cruisers and one with two share three losses as two and one. Ties are broken at random. Splitting or merging fleets can shift a rounding loss by one hull. Loaded transports are hit before empty ones across all your fleets there, so moving cargo into another fleet does not shelter it.

Breaking off is not always a clean escape. A fleet that leaves while the rest of your side fights on gets away for now, but the enemy may still catch it once later. When your whole side has broken off and the enemy stays with armed ships, he may pursue each fleeing fleet. A pursuer whose ships are faster than yours catches you for certain; otherwise it is a roll, likelier the faster he is and the slower you are. A catch is one more exchange for the fleets caught, with die bonuses and carried hits on both sides, and then the battle is over. When both sides break off, nobody pursues. Each enemy empire catches an escaping fleet at most once: in the battle it left, or, if that pursuit failed, in one more attack while the fleet is still leaving the sector. After that the fleet has got away from that empire until it leaves the sector or you give it a new order. Your warships still screen your auxiliaries during a pursuit exchange; only a critical hit reaches past the line. A battle still undecided after 64 exchanges simply ends: nobody wins, nobody retreats, and the next week's encounter rules decide whether the fleets meet again.

A fleet that retreats, or aborts a mission its ROE will not let it fight for, seeks home: it heads for your nearest planet other than the one whose system it is in. With no other planet to go to, it stays in the sector. Its report says why it left — its ROE, or no warships left — and whether it was caught on the way out.

6.7. Planetary Combat

When fleets attack planets through bombardment, invasion, or blitz, different rules apply. Orbital fire at a planet reads its die on a table that compares the two sides' strength, and leftover hits do not carry from round to round. The landing battle between armies has its own rules (see The Landing Battle below). Ground batteries are the planet's shield wall — while they stand, they draw orbital fire and shoot back, protecting the stardock, armies, production, and industry behind them. Only combat ships — destroyers, cruisers, and battleships — contribute bombardment firepower. Scouts, transports, and ETACs do not.

> **WARNING:** Planetary defenses use **focus fire**. Hits from ground batteries bypass the crippled state and directly destroy ships, making them far more lethal than dispersed

ship-to-ship fire. A commander who brings a large fleet to orbit a fortified world will find his ships being picked off one by one by concentrated ground fire.

Each bombardment turn resolves three rounds of fire. In rounds 1 and 2, your ships trade fire with the planet's batteries. While batteries stand at the start of a round, your hits land on the batteries only, and hits beyond what destroys them are wasted. Ships in the stardock are exposed from the next round, the first that begins with no batteries standing. Armies, stored goods, and factories are shielded in these rounds. In round 3, if all batteries have been destroyed, your remaining firepower breaks through to the stardock, then armies, stored goods, and factories. If batteries still stand, round 3 is another suppression exchange and the planet's vulnerable assets survive another turn.

Planetary targets have defense strength just like ships. Destroying a ground battery takes 20 hits, an army 10 hits, and a ship in the stardock as many hits as its own DS. A lone cruiser cannot level a fortified world in a single volley.

This means a well-defended planet takes sustained bombardment over multiple turns before you touch its production. Build batteries to buy time; bring heavy fleets to break through faster.

See Section 7 for the detailed mechanics of bombardment, invasion, and blitz missions. The exact bombardment weights, batteries-only return-fire rule, and combat tables are in Section 12.

6.7.1. The Landing Battle

Armies that land fight on the same table as fleets, army against army, with no force-ratio columns. Each round the **defenders fire first**. Each side rolls one `d10` for its whole army: 0–2 deals 25%, 3–5 deals 50%, and 6–9 deals 100% of its armies' strength. The attackers' losses come off, and the attackers who survive fire back the same way. Rounds repeat until one side has no armies left.

Damage short of a whole army carries into the next round of the same landing and is lost when the landing ends. There is no defender bonus, no homeworld bonus, and no critical hit; firing first is the defender's advantage. The attackers fire only with what survives, so both sides are never destroyed together. Your reports show whole armies lost and remaining; the carried fractions stay hidden.

Capture odds follow the ratio of landed armies to defending armies, roughly the same at any scale. Equal numbers take a world about one time in five. At 1.5 to 1 the odds are about even, and at 2 to 1 the attackers win nine times in ten. Overwhelming numbers still win every time. Appendix B gives the table.

6.7.2. Captured Worlds

A world that falls passes to you with what the fight left standing: its stored goods, production, docked ships, and queued build work. There is no capture bonus, no loss for the kind of attack, and no forgiveness of debt. Your capture report lists the goods, the docked ships, and the queued work you inherit.

A defender can set Scorch Earth to deny a world to the invader. If the world falls with the order set, its production and positive goods are halved, its stardock is emptied, the order is lifted, and production is raised to at least 1.0. A world with no potential stays at 0, debt is untouched, and the build queue is not burned. The capture report says when the defenders had scorched the world. A failed assault leaves the order set.

6.7.3. Failed Assaults

Failure is not defeat. A fleet whose landing fails, or whose Invade is blocked because batteries survived suppression, keeps its survivors in orbit on Hold and receives a failure report. A blocked Invade lands nothing and its armies stay aboard. The fleet does not blockade the world on its own, and like any fleet in orbit it is open to the ordinary encounter rules. A fleet beaten in the orbital battle before it can strike turns for home under the withdrawal rules above; the world's batteries fire on no fleet except one that strikes.

7. Missions and Orders

A fleet always has exactly one standing order. If you issue a new order before maintenance, it replaces whatever the fleet was doing. Missions fall into three categories. *One-shot* missions cause the fleet to travel, perform an action, and revert to Hold Position — you must issue new orders afterward. *Persistent* missions remain active until you replace them or game rules invalidate them (for example, a Join mission is abandoned if the host fleet is destroyed). *Hostile* missions send the fleet into orbit around a target world. It attacks the year it arrives. A bombarding fleet stays in orbit and bombards again each year until you change its orders. An invading or blitzing fleet makes one assault and, win or lose, its survivors hold position in orbit.

No	Mission	Type	Description
00	None	Persistent	Hold position at current location.
01	Move Fleet	One-shot	Travel to a specified sector, then revert to Hold.
02	Seek Home	One-shot	Return to nearest owned planet; retargets if that planet is captured en route.
03	Patrol	Persistent	Move within sector deep space to intercept enemies.
04	Guard Starbase	Persistent	Escort a starbase; fight alongside it.
05	Blockade	Persistent	Watch a world. Attacks assaults, colonizers of an unowned world, and declared enemies.
06	Bombard	Hostile	Damage factories, batteries, armies, stardock contents, and production.
07	Invade	Hostile	Suppress batteries, bombard, then land armies. Requires loaded transports.
08	Blitz	Hostile	Drop armies immediately, dodging batteries. High army risk.
09	View	One-shot	Quick scan of owner and production; the fleet dives in and climbs back out.
10	Scout Sector	Persistent	Watch a sector closely and identify traffic (requires Scout).
11	Scout System	Persistent	Active spy mission into a solar system (requires Scout).
12	Colonize	One-shot	Terraform and claim unowned planet (requires ETAC). ETAC survives for reuse.
13	Join Fleet	Persistent	Chase and merge with target fleet. Abandons if host is destroyed.
14	Rendezvous	Persistent	Meet other fleets at sector. Lowest fleet ID becomes host.
15	Salvage	One-shot	Scrap ships at planet for half their build cost.

7.1. Movement and Arrival

A fleet's speed is the number of sectors it can travel in a year.

Movement is 2.5D. Think of the map as a flat board, with each world sitting one step below it at the center of its sector. Fleets travel across the board. To reach a world, a fleet steps down into its orbit; to leave one, it steps back up. Each step costs one sector of movement, and a fleet can be partway down.

A fleet never moves across and down at once. It climbs out of orbit, flies straight across the map to the center of its target sector, and only then heads down toward the world. A fleet

leaving a planet spends its first sector of movement climbing out, so it covers one sector less in its first year.

When a fleet arrives depends on its mission.

- **Sector missions** (Move, Patrol, Scout Sector, Rendezvous) arrive the year the fleet enters the target sector.
- **World missions** (all the others) continue to the world. Guard/Blockade, View, Scout System, Join, Salvage, Bombard, Invade, and Blitz arrive when the fleet reaches orbit. Seek Home and Colonize finish at the end of the first year the fleet is at least halfway in. Guard Starbase takes up station once the fleet is halfway in and its starbase is there.

A world mission often takes a year longer than a move to the same sector. Distance is measured in a straight line, so three sectors on a diagonal is about 4.2 sectors of travel.

The **ETA** command shows the year a fleet will arrive. For a world mission, answer yes to "Include time to enter system?"

7.2. Mission Details

7.2.1. One-Shot Missions

Mission 1: Move to Sector. A simple transit order. The fleet travels to the destination sector at the speed of its slowest ship, then stops and reverts to Hold Position. You must issue new orders if you want it to do anything else.

Mission 2: Seek Home. The fleet travels to the nearest planet you own. It keeps that planet for as long as you own it, even if another becomes nearer on the way. If you lose the planet while the fleet is en route, the fleet turns at once for the nearest planet you still own, measured from where it is; with none left, it stops and holds where it is. On arrival, it reverts to Hold Position. The game picks the planet; you enter no coordinates. When you order a single fleet that is already in the system of its nearest planet, the game asks "Do you wish this fleet to seek the next closest system?" Yes, the default, sends it to the next closest planet; no keeps it on the planet it is at. If that planet is the only one you own, the game says so and gives no order. In a group order each fleet seeks its own nearest planet without asking.

Mission 9: View a World. A quick look. The fleet dives into the target system, scans for owner and production data, and climbs straight back out into deep space. While it is in the system, the owner's fleets may spot and attack it. It reverts to Hold Position after reporting.

Mission 12: Colonize a World. Requires at least one ETAC (Environmental Transformation And Colonization ship). If the planet is unowned, it is terraformed and claimed. The new colony starts with one garrison army, no treasury, and very low current production. It does not receive revenue or growth until later maintenance turns, and then develops faster under low taxes. The ETAC is not consumed — it survives and can colonize additional planets. If the planet is already owned, the ETAC aborts, reports the owner's identity and production potential, writes that partial result into your Total Planet Database, and waits for new orders.

Mission 15: Salvage. The fleet travels to one of your planets and scraps its ships for half their build cost, rounded up ship by ship, returned to that planet's treasury: 23 points for

a battleship, 8 for a cruiser, 3 for a destroyer, 3 for a transport (loaded or empty), 10 for an ETAC, and 8 for a scout. Armies aboard loaded transports land on the planet, and the fleet is disbanded. If you lose the planet while the fleet is en route, the fleet salvages at the nearest planet you still own instead; with none left, it stops and holds where it is. The game offers the planet nearest the fleet as the default target; if you own only one planet, it takes that planet without asking. A group salvages at one planet.

7.2.2. Persistent Standing Missions

Mission 0: Hold Position. The default idle state. The fleet stays at its current location and takes defensive action based on ROE if hostile fleets approach.

Mission 3: Patrol a Sector. The fleet watches a sector, looking ten times as hard as an ordinary fleet once it arrives. It identifies everything it spots, sends a report, and attacks what the rules in Who Fights Whom allow, as far as your ROE permits. The mission remains active until you assign a new one.

Mission 4: Guard Starbase. The fleet escorts a starbase and fights alongside it: an attack on either one is a battle against both, and the base joins any battle its guard is drawn into as a defender. A guard stays with its base and does not close on the contacts it spots, but it attacks, or joins an attack by your other fleets there, when the ROE odds favor the fight.

Mission 5: Guard/Blockade a World. A strategy of denial. The blockade watches the world five times as hard as an ordinary fleet. It attacks any fleet that comes to bombard, invade, or blitz the world, or to colonize it while it is unowned, and any fleet of an empire you have declared an enemy, including ships leaving the world. Neutral fleets come and go. Blockading another player's world takes your fleet into his solar system, so his fleets there will attack it. It remains active until you assign a new mission.

Missions 10 and 11: Scout Sector / Scout System. Both require at least one Scout ship, and a fleet consisting of a single Scout is the least likely to be detected. Scout Sector is a stealthy watch over the sector: a scout on station looks five times as hard as an ordinary fleet and identifies what it spots, and with ROE 0 it never attacks. Scout System is an active spy run where the Scout penetrates the system to report on ground batteries, armies, current production, stardock contents, and orbiting fleets; entering the system means the owner's fleets there may attack it. Both are persistent missions: the fleet remains on station and generates a new report each maintenance turn for as long as it stays at its assigned sector. If you identify an **In Civil Disorder** fleet in a system that still belongs to that disorder state, the Total Planet Database marks that world's owner as `ICD` even before a full scout/view report is earned.

Missions 13 and 14: Fleet Coordination. Mission 13 (Join Fleet) causes the fleet to chase a specific host fleet and merge with it when they meet. If the host is destroyed before they rendezvous, the joining fleet abandons the mission. Mission 14 (Rendezvous) sends multiple fleets to a sector where the fleet with the lowest Fleet ID becomes the host of the combined force. The rendezvous point remains active so additional fleets can keep merging there.

7.2.3. Hostile (Delayed-Resolution) Missions

> **IMPORTANT:** A hostile fleet attacks during the maintenance in which it reaches orbit (see Section 7.1). The fleet stops in orbit. Bombardment repeats each year until you change the order. An invasion or blitz is a single assault: whether it takes the world, loses its armies, or is called off because the batteries survived, the surviving ships hold position in orbit, and you must order any new attack. A fleet told to attack the world it already orbits attacks at the next maintenance.

A fleet in orbit on a hostile mission has entered the owner's solar system, and it is twenty times easier to see there, so his fleets in orbit are likely to attack it. Before it attacks, it must get past whatever the owner keeps in orbit: his starbase and his fleets there with warships fight it the week it reaches orbit, spotted or not, and your other fleets in that orbit join it under their own ROE. If its ROE will not take them on with the side it has, it turns for home without a shot; if it loses, it is driven off, and his batteries do not fire on it as it goes. Only a fleet that holds the orbit attacks, in that same week. Each fleet attacks on its own as it arrives, so two of your fleets at one world strike one after the other, and the second need not fight defenders the first has beaten.

Mission 6: Bombard a World. Only destroyers, cruisers, and battleships contribute bombardment firepower — scouts, transports, and ETACs do not. Each turn your fleet bombards, the engine runs three rounds of fire. In rounds 1 and 2, your ships exchange fire with ground batteries — while batteries stand, your hits destroy batteries only and the excess is wasted, and armies, stored goods, and industry are shielded behind the battery wall. Each battery takes 20 hits to destroy, each army 10, and each docked ship its own DS. Docked ships are exposed from the first round that begins with no batteries standing. In round 3, if batteries have been eliminated, your firepower breaks through to the stardock, then armies, stored goods, and finally industry. If batteries still stand after round 2, round 3 is another suppression exchange and the planet's production survives. Bombardment persists each turn until you issue new orders. Use it to grind down a world's defenses before invasion, or to deny resources to an enemy over time.

Mission 7: Invade a World. A three-stage deliberate assault. First, combat ships exchange fire with ground batteries in orbital suppression — transports cannot land until all batteries are destroyed. Once batteries are gone, surviving combat ships fire on the defending armies to soften resistance before landing. Softening fire is matched against the garrison's full strength (10 AS per army), and each army destroyed takes 10 hits. Unlike bombardment, invasion softening targets armies only — industry and stored goods are preserved because the goal is to capture the planet with its production intact. However, orbital softening can destroy at most **half** of the defending army stack; at least half of the original defenders must still be fought on the ground. Finally, transports land their armies and the landing battle runs in rounds until one side is wiped out. The defenders fire first in every round, and one side always survives. Capture requires destroying all defending armies, after which your surviving armies become the new garrison. If the batteries survive suppression, no troops land and the armies stay aboard. Win, lose, or called off, the fleet then holds position in orbit.

Conquered planets need approximately two turns before they are fully converted to your production.

Mission 8: Blitz a World. Transports drop armies immediately in a fast assault that bypasses the full orbital suppression sequence. Escorting combat ships provide brief cover fire, but surviving batteries fire directly on descending transports, causing heavy losses. A fleet of loaded TT* may attempt a blitz even without escorting warships, but then it brings no orbital firepower of its own. The owner's ships without warships do not prevent that attempt, but his starbase or any fleet of his with warships in orbit stops it: with nothing to fight them, the transports turn for home. Once on the surface, armies fight the same landing battle as an invasion, defenders first, until one side is wiped out. If you take the planet, surviving ground batteries transfer intact to your control. The blitz preserves industry but carries high risk to your armies and transports — a 2:1 army advantage or better is recommended. Win or lose, the fleet then holds position in orbit. Choose blitz when the planet has few or no batteries and you want to preserve its industry, or when speed matters more than casualties.

8. Interface and Commands

The game is organized around four primary menus. From the **Main Menu**, you access General Command (**G**) for autopilot, diplomacy, and reports; Planet Command (**P**) for economy and production; Fleet Command (**F**) for ship movement and missions; Information Database (**I**) to review known planet data; and View Starmap (**V**) for a graphic map of the galaxy.

8.1. Visual Themes

The `nc-game` client supports several visual themes. In a local session, open **C>olor Theme** from the Main Menu or First Time Menu to choose one. Your last local choice is remembered for that empire in that campaign.

In BBS door mode, the game keeps the classic **A>nsi color ON/OFF** toggle. Each session starts from the `mag16` theme so ANSI16 terminals stay stable. Press **A** to switch between that view and monochrome for the current session. Saved local theme preferences do not apply in door mode.

8.2. General Command

General Command handles empire-wide business. Autopilot (**A**) lets the computer mind your defenses if you miss turns. By default, autopilot turns on after three missed turns. Your first real return that year — logging into `nc-game`, entering through `nc-door`, or submitting a valid turn file — turns that inactivity autopilot back off. Manual autopilot stays on until you change it yourself. While autopilot runs, each year it sends every fleet on Hold Position to the planet of yours that is best for its distance and production. Warships already in orbit there take Guard/Blockade, raising an ROE of 0 to 6. Any fleet of yours on Guard/Blockade that sits still in orbit with a starbase of yours that has no escort escorts that starbase, whether or not autopilot gave it the order. Fleets with any other order are left alone. Diplomacy (**E**) lets you mark other empires as Neutral or Enemy. Messages (**C**) lets you write to other empires. In the message editor, **^E** sends, **^X** cancels, and **^G** shows help; **?** types a question mark, as it does in name fields. Messages reach their recipients at the next maintenance. Until then, the ones you send this turn sit at the top of your inbox, marked **OUT**; **Enter** reads one and **D** cancels it. **D** on the recipient list opens the same queued messages with the same keys.

To keep messaging civil, you may send no more than three messages to any single opponent per turn. In a four-player game, for example, that is up to twelve outgoing messages in a turn. Messages and reports are never automatically purged — they accumulate in your inbox across turns until you remove them yourself. The inbox supports type and year filters to help you find older items, and pressing **D** on a selected item prompts for deletion, defaulting to yes. General Command also offers a bulk delete to clear all messages at once. New reports and messages from the most recent maintenance turn are presented one by one through the scrolling intro review when you log in, giving you another opportunity to read and delete before reaching the main menu.

The empire rankings table shows each joined empire in one of three states: **Active**, **MIA**, or **Defeated**. **MIA** means inactivity autopilot is currently running because that player missed three consecutive turns. **Defeated** means the empire has been eliminated from active command.

8.3. Defeat, Recovery, and Victory

Losing your last planet does not always defeat you immediately. If you still have a recovery path, you remain **Active** and receive a **three-turn recovery window** to reclaim a world. A recovery path means at least one loaded troop transport (TT*) somewhere in your surviving fleets, or at least one ETAC while any unowned planet still exists anywhere on the map. If you retake or colonize a world before the window expires, the countdown clears and your empire continues normally.

If your last recovery force is destroyed while you are planetless, or if the three-turn recovery window expires first, your empire becomes **Defeated**. Fleet Command sends you a final defeat report, and you receive one last review-only login so you can read the closing reports and messages. After that final review, you may no longer enter the campaign.

When you eliminate another empire, Fleet Command reports that you delivered the final blow. This is separate from overall game victory. The game ends only when one empire is recognized as Emperor and no other serious contender remains. At that point every still-playable empire receives a game-over report naming the victor. The winner may continue to log in in **survey mode** to inspect the final state of the galaxy, but may not issue orders or submit turns. All other players receive one final review-only pass and are then blocked from further play.

8.4. Planet Command

Planet Command controls your economy and ground operations. Tax (**T**) sets the empire-wide tax rate. From the main Planet Command menu, Scorch Earth (**S**) sets or rescinds the order that wears down your own industry to deny it to an invader (see Section 5.9). Build (**B**) spends production points on ships, defenses, or starbases. Commission (**C**) assigns newly built ships from stardock into active fleets. **Mass Commission** (**M**) commissions every ship and starbase currently waiting in stardock. Load and Unload (**L** / **U**) move armies between the planet surface and troop transports.

The **Planet List** is the fast row-centric operations screen for owned worlds. Once you open it, the highlighted planet becomes the working row for the most common actions: Build (**B**), Display Queue (**D**), Abort Builds (**A**), Mass Commission (**M**), Commission (**C**), Load / Unload armies (**L** / **U**), and Scorch Earth (**X**). On that screen, **S** is reserved for **Sort**, while **I** or **Enter** opens planet information for the selected row. Owned-planet information includes the planet's **Budget** as well as its **Treasury**.

8.5. Fleet Command

Fleet Command controls your ships in space. Mission (**O**) assigns missions 0–15. ROE (**C**) changes a fleet's rules of engagement, ID, or speed. A speed change takes 1 up to the fleet's maximum and touches nothing else; a fleet on Hold, or already at its target, keeps speed 0. Merge (**M**) combines fleets that are in the same sector. Transfer (**T**) moves individual ships between fleets.

The **Fleet List** is also the bulk-fleet work screen. It now includes a **Sel** column. Press **Space** on a fleet row to check or uncheck it. When one or more fleets are checked, **O** assigns one

mission to the checked set, **C** changes their shared ROE or speed, **M** merges the checked fleets using the lowest Fleet ID as the host, and **T** opens ship transfer for a checked pair. Row-based commands such as **Review**, **ETA**, **Detach**, **Load**, and **Unload** still use the highlighted fleet.

Crippled ships show in the Ships cell of the Fleet List, in **Review**, and in **Detach** and **Transfer**, always in the notation of Section 4.2.1. **Review** adds the short legend under the composition of a damaged fleet. Your maintenance report says when ships have recovered.

Detach (**D**) and **Transfer** (**T**) stage ships one class at a time. Type a class code (`BB`, `CA`, `DD`, `TT*`, `TT`, `SC`, or `ETAC`), then a quantity. A plain quantity such as `3` takes healthy ships first and takes crippled ships only when the class has too few healthy ones. A quantity followed by a bang, such as `3!`, takes exactly three crippled ships; the game refuses it when the fleet has fewer, and it never fills the gap with healthy ships. Among crippled ships, those crippled most recently go first, then those with the most recovery time left. The **Staged** line shows the ships that will move, in the same notation: `CA3!1` is three cruisers, one of them crippled. Moving crippled ships never repairs them or restarts their recovery, and each keeps the time it has left.

8.6. Building and Commissioning

Each planet keeps a build queue, and your **budget** is the only limit on it: you may order any number of units of any kind, so long as the budget covers them. During maintenance, a planet processes as many queued build points as its current per-turn build capacity allows. Small orders may finish in one maintenance turn, while larger ones can stay queued across multiple years until the remaining cost reaches zero. As enough points are applied to complete individual units, ships and starbases move to **Stardock** — a holding area on the planet where they sit idle and vulnerable until commissioned — even if other units from the same order remain queued. Ships are commissioned into numbered fleets, while starbases are commissioned individually and managed through their own Starbase Command submenu. Armies and ground batteries, by contrast, deploy directly to the planet surface and do not pass through stardock.

Aborting the queue releases the points still unpaid. Points already spent on a part-built unit are not returned.

A planet without a starbase can spend up to its Production, rounded to the nearest point, in a single turn. A planet with an orbiting starbase can spend up to **5x** its Production, drawing from its treasury (see Section 5.6). The build screen shows **BUDGET** — your treasury capped by build capacity, minus what you have already committed this turn.

> **NOTE:** The build queue, stardock, and treasury are all linked. If stardock is full for a given unit type, that order stops drawing points. Blocked orders do not drain your treasury — but they also do not free capacity for other work. Commission your ships promptly to keep the pipeline moving.

WARNING: Troop transports are built empty. You must manually load armies onto them before sending them into battle.

WARNING: Stardock contents are a prime target for enemy bombardment. Commission your ships promptly or risk losing them before they ever see combat.

NOTE: The starmap can be exported as a TXT file, a CSV grid, and a CSV details sheet for offline planning. Local Rust-client play can export it directly from the in-game starmap view, and BBS operators can hand the exported files to players out of band if they want offline planning aids.

9. Strategy

9.1. Early Game: The Land Grab

The opening turns are a race for territory. ETACs are your most valuable early asset — grab every raw planet you can find before your rivals do. Push lone destroyers forward as pickets to make early contact, but use true Scouts when you need stealth reconnaissance. Keep your tax rate at or below 65% to avoid damaging production, and drop taxes even lower on new colonies so they develop quickly. The temptation to tax at 100% for immediate cash is strong, but it cripples long-term growth.

9.2. Mid-Game: Consolidation

Once the easy colonies are claimed, the game shifts to fortification and intelligence. Build starbases on your best worlds to boost both defense and production capacity. Never attack a planet blindly — use Scout ships on Mission 11 to count enemy batteries and garrison strength before committing forces. This is the "get tough" phase: when raw planets are gone, the only way to grow is war.

9.3. Late Game: Total War

In the endgame, fleet composition and denial matter more than raw numbers. Mix destroyers, cruisers, and battleships in every fleet to trigger the combined arms bonus and distribute damage across hull types — pure battleship fleets are expensive and miss the bonus. If you cannot hold a planet, scorch it. If you cannot take a planet, blockade or bombard it into uselessness. And in a 25-player galaxy, diplomacy is not optional: you cannot fight everyone at once. Form alliances, even temporary ones, and break them only when the timing is right.

10. Historical Context

The BBS Era (1990–1992)

The original game emerged between 1990 and 1992 as a "door game" for Bulletin Board Systems. In an era before the World Wide Web, players dialed into servers over phone lines to play strategy games against dozens of strangers. Everything ran through rigid 80x25 text terminals — every menu, every star map, every battle report squeezed into that tiny viewport. It stood alongside classics like *TradeWars 2002* and *Solar Realms Elite*, but was distinguished by its depth, its hands-off design, and the sheer scale of its campaigns.

What Made It Special

Most multiplayer games of the era demanded constant attention. Esterian Conquest was different. You checked in once a day, submitted your orders, and went about your life. Overnight, the engine processed every empire simultaneously — fleets moved, economies grew, battles resolved, and alliances were tested. When you logged in the next day, a stack of reports was waiting. Campaigns ran for months, and the stories they produced — surprise invasions, desperate blockades, betrayals at the worst possible moment — were the kind that stuck with players for years.

The Rust Port (2026)

This edition rebuilds the game for modern machines while keeping the old campaign rhythm intact. The core rules were recovered from the original game and manuals, then rewritten into a clear modern engine. Where the old game hid things behind opaque internals, this edition uses explicit documented rules instead. If you played the original game on a BBS, it should feel familiar. If you are new to it, this manual gives you the rules straight.

11. Appendix A: Economy Formula Reference

This appendix collects the exact economy formulas in one place.

11.1. Yearly Tax Revenue

```
revenue = present_production * tax_rate / 100
```

Maintenance credits this revenue to the planet's treasury after the year's growth and any high-tax penalty, so `present_production` here is the updated value. Nothing is rounded: production and the treasury keep their fractions. The Revenue shown on the planet and empire screens is next year's figure, rounded to the nearest whole point, on the assumption that the tax rate, the owner, and the starbase stay as they are. Empire Revenue is the sum of those figures over all owned planets.

11.2. Yearly Growth

```
gap = potential_production - present_production
tax_headroom = 100 - min(tax_rate, 95)
growth = gap * tax_headroom / 400
```

Growth never exceeds the gap, and there is no yearly minimum.

11.3. High-Tax Penalty Above 65%

```
if tax_rate > 65:
penalty = present_production * (tax_rate - 65) / 500
```

Final yearly Production is:

```
present_production = present_production + growth - penalty
```

and never more than Potential. At a steady tax rate above 65%, Production settles at `potential * a / (a + b)`, where `a = tax_headroom / 400` and `b = (tax_rate - 65) / 500`. For Potential 100 that is 88.2 at 70% tax (income 61.8) and 85.8 at 71% (income 60.9). Settled income is highest at 65% and falls with every point above it.

11.4. Starbase Growth Bonus

A commissioned starbase boosts growth at low and moderate tax rates, and the bonus fades to nothing by `65%`. Only a base of yours resting in orbit over the world when the year begins counts. A base under way, even one that arrives during the year, gives no growth bonus, nor does a base in deep space. More than one base does not add to the bonus.

```
bonus = 0.5 if tax_rate <= 50
bonus = (65 - tax_rate) / 30 if 50 < tax_rate < 65
bonus = 0 if tax_rate >= 65
growth = gap * tax_headroom / 400 * (1 + bonus)
```

The bonus does not change the high-tax penalty.

11.5. Build Capacity, Treasury, and Budget

Per-turn build capacity is:

```
build_capacity = round(present_production) without starbase
build_capacity = round(present_production) * 5 with starbase
```

Production is rounded to the nearest whole point. Here "with starbase" means one of your bases in orbit over the world and bound there, or descending to it. A base ordered elsewhere, or one in deep space, does not count. One base is enough; more add nothing.

A planet's **treasury** accumulates unspent production points across turns, with their fractions. You can spend only its whole points:

```
spendable = floor(max(0, treasury))
budget = min(spendable, build_capacity)
```

A negative treasury is a debt. It stays negative, and later revenue pays it down.

The BUDGET field on the build screen shows how many points remain after committed queue entries are subtracted. Maintenance deducts only the build points actually processed that year; any remaining build cost stays queued for later turns, and blocked builds do not consume the treasury. Aborting the queue releases the points still unpaid, not points already spent.

11.6. New Colonies

A colony starts with `present_production = min(3, potential_production)` and no treasury. This applies only when the colony is founded.

11.7. Scorch Earth

While a planet's Scorch Earth order is in force, each yearly pass, after the build queue and in place of growth and revenue, does this:

```
present_production = max(1, present_production * (0.30 + Random(20) / 100))
treasury = min(treasury / 10, sqrt(treasury)) if treasury > 0
```

`Random(20)` is a whole number from 0 to 19. A planet with Potential 0 stays at Production 0. A debt (a negative treasury) is left as it is. Potential Production is unchanged, and the planet's Revenue reads 0.

12. Appendix B: Combat Tables and Formula Reference

This appendix collects the combat reference tables in one place.

12.1. Rules of Engagement Thresholds

ROE	Force Requirement	Behavior
00	Never engage	**Pacifist**: Flee from all hostile fleets.
01	Enemy defenseless	**Opportunist**: Engage only if the enemy has no combat capability.
02	4:1 or better	**Very Cautious**: Engage only with overwhelming advantage.
03	3:1 or better	**Cautious**: Engage only with strong advantage.
04	2:1 or better	**Favorable**: Engage with clear superiority.
05	3:2 or better	**Confident**: Engage with moderate advantage.
06	1:1 or better	**Balanced**: Engage equal or inferior forces.
07	Even if outgunned 3:2	**Bold**: Accept moderate disadvantage.
08	Even if outgunned 2:1	**Aggressive**: Accept significant disadvantage.
09	Even if outgunned 3:1	**Reckless**: Accept severe disadvantage.
10	Always	**Suicidal**: Attack regardless of the odds.

12.2. Unit Combat Values

The combat tables use a **10x internal scale**. That keeps attrition granular and lets crippled light ships keep contributing fire.

Unit	AS	DS	Notes
Destroyer	10	8	Fast raider and line support
Cruiser	30	30	Balanced brawler
Battleship	90	100	Primary battle line
Scout	0	10	Non-combat hull
Transport	0	10	Non-combat hull
ETAC	0	20	Colonization hull
Starbase	100	120	Heavy orbital defender
Battery	90	20	Planetary defense
Army	10	10	Ground combatant

12.3. Fleet Battle Effectiveness

Modified d10	Effectiveness
`0–2`	25% of AS
`3–5`	50% of AS
`6–9`	100% of AS

Fleet battles, the pursuit exchange included, read the modified `d10` on this table. The force ratio plays no part in a volley; it decides only whether a fleet attacks and whether it stays, as attack strength against attack strength, a starbase counting 100.

12.4. Fleet Battle Die Modifiers and Hit Formula

- Mixed fleet (at least two of destroyers, cruisers, and battleships): `+1`
- Starbase on your side: `+1`
- Surprise (the defending empire had not spotted the attacker in that sector and layer): `+1` to the attacker, in the first exchange only
- Total modifier: at most `+2`; a modified roll above `9` counts as `9`
- Pursuit exchange: the same modifiers, except surprise, which it never gets

```
hits = ceil(total_AS * effectiveness)
```

An unmodified `9` on the `d10` is a critical hit and destroys one more ship outright, a crippled ship first.

12.5. Damage Steps and Carried Hits

- Crippling a nominal ship costs its full DS.
- Finishing a crippled ship costs its full DS again.
- Execution fire that destroys a nominal ship pays both: `2x DS`.
- Hits a pool cannot spend carry over, in that pool, to the side's next exchange in the same battle, including the pursuit exchange.
- Suppression and execution hits carry separately.
- Carried hits are lost when the battle ends: by destruction, by a side breaking off, or at the 64-round limit. The next battle starts from zero, a pursuit on a later week included.
- A crippled hull stays crippled after the battle and fights at half its AS (a crippled starbase at 50) in every later battle, the attack decision and the ROE checks included. It recovers on its own at the end of the second year after the year that crippled it, and fights whole from the third, for every class. A starbase brings it back a year early when the hull was crippled before the year began and its fleet rested in orbit of your own world beside that starbase for the whole year. Finishing fire takes the newest damage first, then the hulls with the most time left. Detach and Transfer take healthy hulls first for a plain quantity and crippled hulls, newest damage first, for `n!`.

12.6. Planetary Force Ratio to CRT Column

Bombardment, invasion suppression and softening, and blitz cover and landing fire read the `d10` on the ratio CRT below. The landing battle between armies does not; see Landing Battle.

Force Ratio	CRT Column
`< 0.5`	Disadvantaged
`0.5 .. < 1.0`	Pressed
`1.0 .. < 1.5`	Even
`1.5 .. < 3.0`	Advantaged
`>= 3.0`	Overwhelming

12.7. Planetary Combat CRT

d10	Disadvantaged	Pressed	Even	Advantaged	Overwhelming
0	0.00	0.25	0.50	0.75	1.00
1	0.25	0.50	0.75	1.00	1.25
2	0.25	0.50	1.00	1.25	1.50
3	0.50	0.75	1.00	1.25	1.50
4	0.50	0.75	1.00	1.50	1.75
5	0.50	1.00	1.25	1.50	1.75
6	0.75	1.00	1.25	1.50	2.00
7	0.75	1.00	1.50	1.75	2.00
8	1.00	1.25	1.50	1.75	2.00
9	1.00	1.50	1.75	2.00	2.50

12.8. Planetary Column Shifts and Hit Formula

- Mixed `DD/CA/BB` fleet in bombardment or invasion suppression: `+1` CRT column
- Final columns are clamped to the table bounds

```
hits = ceil(total_AS * CRT_multiplier)
```

An unmodified `9` on the `d10` is a critical hit and forces one extra bypass loss allocation.

12.9. Bombardment and Planetary Fire

Only destroyers, cruisers, and battleships contribute bombardment attack strength:

- Destroyer bombardment AS: `0.5x`
- Cruiser bombardment AS: `1.0x`
- Battleship bombardment AS: `1.5x`

Planetary return fire is:

```
return_fire_AS = battery_AS
```

Planetary return fire from batteries uses the **focus fire** rule. Hits bypass the crippled state and allocate directly to the destroyed pool by paying the full `2x DS` cost per ship.

Orbital hits on a world pay each target's DS on the same 10x scale:

- Ground battery: `20` hits
- Army: `10` hits
- Ship in the stardock: its own DS from the unit table (docked batteries `20`, armies `10`)
- Stored goods and factories: remaining hits are divided by `10`, and each point then destroys `25` stored goods and `1` factory

Hits below one unit's cost do not destroy it, and partial hits do not carry over to the next round. Once the stardock is exposed, hits too few for the next docked item pass on to the next stardock entry. Invasion suppression and blitz cover fire pay the same battery cost and never reach the stardock.

Blitz landing fire is one exchange of the surviving batteries' AS against the escorts' bombardment AS. It is focus fire aimed at the descending transports first: each transport destroyed costs `20` hits (2x its DS) and takes its army with it, and any hits left over fall on the escorts.

Each bombardment turn runs three rounds. Batteries shield the stardock: an exchange that begins with batteries standing hits batteries only, and hits beyond what destroys them expire. Docked ships are exposed from the next exchange.

- **Rounds 1–2 (Suppression):** While batteries stand at the start of the round, attacker hits go to batteries only; with none standing, they go to the stardock. Batteries fire back each round. Armies, stored goods, and industry are shielded.
- **Round 3 (Breakthrough):** If batteries reached zero before this round, attacker hits go to the stardock, then cascade into armies, stored goods, and industry. If batteries still stand, round 3 is another suppression exchange.

Invasion uses one suppression exchange against batteries. If batteries are cleared, the softening pass targets armies only — industry and stored goods are not damaged during invasion. Its CRT column compares bombardment AS against `armies x 10`. Orbital softening may destroy at most half of the defender's starting armies, ensuring a meaningful landing battle whenever a world began the assault with a garrison. Once armies land, the landing battle in invasion and blitz is fought as described next.

A fleet whose landing fails, or whose Invade is blocked by surviving batteries, holds in orbit on Hold with a failure report. It does not blockade the world automatically.

12.10. Landing Battle

Armies (AS 10, DS 10) fight on the same table as fleet battles, unmodified, in rounds. In each round the defenders roll and fire first, the attackers' losses come off, and the surviving attackers roll and fire back. A side with `n` armies deals `n x 1`, `n x 2`, or `n x 4` quarters of an army on a roll of `0–2`, `3–5`, or `6–9`; four quarters destroy one army. Damage short of an army carries into the next round of the same landing and is lost when the landing ends. There is no defender modifier, homeworld bonus, or critical hit, and one side always survives. Rounds repeat until one side has no armies.

Attackers vs defenders	Capture
1 vs 1	33.6%
2 vs 1	85.1%
3 vs 2	55.6%
3 vs 1	99.4%
5 vs 5	22.6%
10 vs 10	19.9%
11 vs 10	27.6%
15 vs 10	56.1%
20 vs 10	91.8%
20 vs 20	19.0%
40 vs 20	92.3%

The armies that land are those left after blitz landing fire, and the defenders are those left after invasion softening. Capture odds follow that ratio at every scale; overwhelming ratios still win every time.

13. Appendix C: Preservation and Original Sources

This edition preserves the game in a playable modern form. The aim is simple: keep the campaign rules legible, playable, and documented.

13.1. Source Hierarchy

This manual is the authoritative player manual for the Rust edition of Nostrian Conquest.

The preserved originals in `original/v1.5/` remain historical references and an ambiguity fallback:

- `ECQSTART.DOC` — Quick-start guide
- `ECPLAYER.DOC` — Detailed player manual
- `ECREADME.DOC` — Release and package information
- `ECGAME.EXE` — The original 1992 player client
- `ECMAINT.EXE` — The original yearly maintenance program
- `ECUTIL.EXE` — The original sysop utility for game initialization and management

13.2. Preservation Policy

- This manual is the authoritative player-facing manual for the Rust edition.
- The original manuals are preserved historical references and an ambiguity fallback for classic intent and terminology.
- The original DOS binaries remain the final compatibility check.
- This edition keeps the player-visible classic behavior that matters.
- When an exact classic formula is still unknown, this manual states the rule plainly instead of pretending otherwise.
- When the preserved originals clarify an ambiguity, that clarification should be folded back into the current manuals/specs rather than left only in the legacy `.DOC` set.

13.3. BBS Drop File Compatibility

Rust BBS hosting uses `nc-door`, not the old DOS binary path. It reads `DOOR32.SYS`, `DOOR.SYS`, and `CHAIN.TXT` directly. For a player, the practical point is simple: log into the board, launch the door, and play. If you are the sysop, see the **Sysop Manual** for setup details.

13.4. This Manual

This manual combines the original player guidance with the appendix reference tables in Section 11, Section 12, and Section 14. The main body stays player-facing. The appendices collect formulas, tables, and list-screen codes.

14. Appendix D: Table Filtering and Sorting

The main list screens all use the same command-line filter system. This lets you cut a long table down to the exact rows you want instead of paging through dead weight.

One filter is active at a time on each table. If you choose a new filter, it replaces the old one. If a filter matches nothing, the table stays filtered and tells you no rows match.

14.1. Filtering Procedure

1. Open the table you want.
2. Press `F`.
3. Type the column code, the visible column name, or the shortest unique prefix, and press `Enter`.
4. Type the value for that column and press `Enter`.
5. Type `all` at the column prompt to clear the current filter.

NOTE: `Q` or `Esc` cancels the current filter prompt without changing the active filter.

If your prefix matches more than one code, the command line stays open and shows the matching codes so you can narrow the entry.

14.2. Value Rules

- **Text columns:** Enter plain text. Matching is case-insensitive and looks for that text anywhere in the cell.
- **Number columns:** Enter a bare number for an exact match, or use `>`, `>=`, `<`, `<=`, `=`, or `!=`.
- **Coordinate columns:** Enter `xx,yy` for one exact sector, or `xx,yy/r` for a radius filter.
- **Database unknown values:** Enter `?` to match worlds where that value is still unknown.

Examples:

- Fleet list, `ord`: `holding`
- Fleet list, `sel`: `yes`
- Fleet list, `roe`: `>=4`
- Planet list, `coo`: `12,7/3`
- Total planet database, `own`: `#3`
- Total planet database, `max`: `>=100`

14.3. Sorting Procedure

1. Open the table you want.
2. Press `S`.
3. Type the column code, the visible column name, or the shortest unique prefix, and press `Enter`.
4. Press `S` again and submit the same code, or just press `Enter` on the default code, to flip `ASC`/`DESC`.

NOTE: On the Total Planet Database, `rng` or `range` is also accepted at the sort prompt to sort by distance from a chosen sector.

The active sort and active filter both appear in the table title.

14.4. Fleet List Codes

Code	Column	Notes
`id`	Fleet ID	Fleet number
`loc`	Location	Current sector
`ord`	Order	Also accepts `holding`, `moving`, and `combat`
`tar`	Target	Mission target sector
`spd`	Speed	Current speed
`eta`	ETA	Text match on the ETA column
`roe`	ROE	Rules of engagement value
`ars`	Armies	Loaded armies
`shi`	Ships	Ship and force summary text
`sel`	Selected	Use `yes` or `no`

14.5. Planet List Codes

Code	Column	Notes
`coo`	Coord	Planet coordinates
`pla`	Planet	Planet name
`max`	Max	Maximum production
`cur`	Curr	Current production
`trs`	Points	Stored treasury points
`bdg`	Bdgt	Build budget
`rev`	Rev	Revenue
`gro`	Grow	Growth
`bui`	Queue	Build queue size
`sta`	Dock	Docked ships
`sbs`	SBs	Friendly starbases
`ars`	ARs	Planet armies
`gbs`	GBs	Ground batteries

14.6. Total Planet Database Codes

Code	Column	Notes
`coo`	Coord	World coordinates
`pla`	Planet	Known planet name
`own`	Owner	Known owner text such as `#3` or `Unowned`
`max`	Max	Known maximum production
`see`	Seen	Last year seen
`ars`	ARs	Known armies
`gbs`	GBs	Known ground batteries
`sbs`	SBs	Known starbase count
`cur`	Curr	Known current production
`trs`	Points	Known stored points
`sco`	Scout	Last scout year
